j.e.wilson@unsw.edu.au

Background

21st century research approaches in the biological sciences continue to progress at an ever-increasing pace. Advances in computer technologies have resulted in exponential increases in the rate at which biological data are collected, accumulated, disseminated and applied. Biology education has remained predominantly content-centric, focused on prescribed activities with little autonomy, and pedagogies have remained stagnant in comparison to the implications of research outcomes (National Research Council 2003; Handelsman, Ebert-May, Beichner, Bruns, Chang, DeHaan, Gentile, Lauffer, Stewart, Tilghman, and Wood 2004). There is a critical need for evidence-based reform to align the link between current research and pedagogical practice. This project addresses this need through the creation of collaborative learning communities from a crucial starting point: ‘thinking about thinking’, i.e., the enhancement of learning through individual and group reflection and analysis of the scientific inquiry process.

This project aligns science teaching and learning to the scientific research method using an approach that enhances student engagement and aligns desired learning outcomes with professional practice. The aim was to shift the assessment-driven motivation of students toward intrinsic motivation through collaborative inquiry, and encourage them to reflect on their own learning as they integrate theory with practice. The approach centres on the creation of learning communities structured to facilitate students’ metacognitive awareness of both individual and collaborative learning processes. The integration of reflection, analysis and critique of process (as opposed to outcome) into a research-based e-poster project enhances student learning by reinforcing the iterative process of the scientific method. The strategic structure of the online and face-to-face components of the collaborative inquiry process acknowledges and builds upon the disciplinary, cultural, and social diversity of the class.

The context and setting

The second year undergraduate course, Fundamentals in Microbiology & Immunology (MICR2201) has a large enrolment of 280 students. The students represent a diverse range of backgrounds, including majors in Microbiology, Medical Microbiology and Immunology, Molecular Biology, Food Science and Nutrition, Biotechnology, Nanotechnology, Bioinformatics, Biochemistry, Genetics, and Marine Science. The course forms a cornerstone of the foundational theoretical and practical training for many students in the Faculty of Science at the University of New South Wales, and it is a prerequisite for many higher level courses in the life sciences. The course is comprised of 2 x 1 hour lectures, 1 x 1 hour tutorial, and a 1 x 3 hour laboratory practical per week. The tutorials (10 – 15 students) and laboratory practicals are taught by experienced postgraduate tutors, many of whom have taken this course in the past. Each group of students remains with the same tutor for the tutorials and labs.

Integration of theory and practice

Significant changes have been implemented in the course curriculum since 2003 to facilitate conceptual understanding and deep learning. This includes the creation of a WebCT component that reinforces foundational understanding, and facilitates laboratory investigations by linking theory to practice. As this is the first exposure to the microbiology laboratory for most students, basic microbiological skills are progressively taught in synchrony with the fundamental concepts of the lectures. A significant portion of the formative assessment includes an individual research project conducted in parallel with the basic laboratory component. The aim of the
students’ research project is to isolate and identify a single bacterial genus (fondly referred to as their ‘bug’) from an environmental sample through the practical application of students’ conceptual understanding of bacterial metabolism, morphology and physiology. The application of their theoretical understanding is central to the development of their rationale for determining experimental process at each stage of their research project, and the interpretation of these processes.

The formative assessment for the research project has, in years past, followed a traditional approach that included a formal scientific paper for the bug research project, laboratory quizzes, and evaluation of laboratory notebooks. Two years ago, we developed a learner-centred assessment component called the ‘Bug Book’, which allows flexibility in mapping individual progress. The Bug Book encourages students to put their own creative imprint on the documentation of their research process to suit their learning styles, and emphasis is placed on reflective process rather than experimental outcomes. The impact of the Bug Book has been an enhancement of students’ intrinsic motivation, fostered by a sense of ownership of their work and self-directed learning. These outcomes reaffirm the importance of contextual learning environments that facilitate enhanced engagement and deeper learning in students (Ramsden 1992). The Bug Book has also continued to be a valuable reference and learning resource for students, who continue to utilise them in their subsequent microbiology courses. Such constructive alignment of a student-centred assessment task promotes the enhancement of teaching and learning (Biggs 1996).

**Fostering collaborative learning communities**

A hallmark of scientific research is the collaborative and multidisciplinary nature of research inherent to the process. Emphasis on the process of inquiry engages students in an authentic learning experience (Takayama 2005). Whilst we have been aware of the challenges in fostering authentic inquiry through group work in a large class setting, our goal was to develop a truly collaborative learning experience in the context of the bacterial isolation project. Student feedback on the Bug Book highlighted the marked impact that a learner-centred assessment project has on intrinsic motivation. We therefore developed a framework for collaborative learning within a large class that integrated reflection, evaluation and critique of both scientific process and learning experience within the assessment. The framework was strategically designed to provide relevance and application, key criteria for authentic learning experiences (Chinn and Malhotra 2002; Herrington and Herrington 1998; Kolb 1984; Meyer 1992). In so doing, the goal was to achieve constructive alignment between the goal (to make ‘scientific thinking visible’) and learning outcomes within the context of a team inquiry project.

The traditional model that is used to teach the scientific method invariably follows a linear approach (Figure 1).

This conceptually linear approach, which leads toward a singular endpoint, reinforces a perception amongst students that the ‘outcomes and conclusions’ are the most important elements of the research process. This belief is perpetuated through the honours year of the undergraduate curriculum. However, scientific research involves continuous reflection, analysis, and communication, and this evaluative process contributes to ongoing development and discovery.

We have created our own model to develop a reflective, iterative approach to engage students in an inquiry process that is more cognisant of scientific professional practice (Figure 2).

This model represents a more authentic process with regard to the learning and teaching of scientific inquiry and equally importantly, a framework for assessment.

![Figure 1. Traditional linear model](image1)

![Figure 2. Our own model to develop a reflective, iterative approach to the teaching and learning of scientific inquiry](image2)

**Approach**

**The progressive e-poster**

The goal for MICR2201 was assessment for deep learning and promotion of metacognitive awareness of inquiry linked to the learning process. The progressive e-poster is a group assessment project that maps student learning on the process of collaborative inquiry. The e-poster modifies a traditional mode of communication of research in the biological sciences (‘the poster’). It is distinct from the
The laboratory research project and the progressive e-poster were tightly linked to actively and intellectually engage students throughout the entire course. This engagement was strengthened through the collaborative framework of the learning process, and the challenge of open-ended inquiry. The outcomes from the e-poster are indicative of students’ conceptual development regarding the iterative process of authentic inquiry. Several teams took the initiative to create their own original concept maps to document the evolution of their conceptual schema. Such documentation, dissemination, and integration of feedback into the continued self-reflection and critique at the group level are indeed indicative of scholarship. The progressive learning journey of one group may be viewed at: http://www.cfkeep.org/html/stitch.php?s=15996728386727 &id=79371591451924.

The challenge of developing and revising their own research approach created an engaging level of motivation for students. As an extension of this learner-centred approach, the e-poster provided an opportunity for creative teamwork aligned to the learning experience. Student responses to a Likert scale survey (Table 1) indicate that the e-poster primarily encouraged students to work collaboratively and to learn from their peers. As a formative assessment approach, the students also recognised the e-poster as a learning tool.

One of the goals in this course is to foster students’ metacognitive awareness; i.e., thinking about their learning. The responses from the survey indicate that this desired outcome was not entirely achieved. Our interpretation is that the focus on group collaboration may have precluded individual introspection. In addition, students did not believe that the e-poster facilitated their problem-solving skills. We had initially assumed the e-poster would strengthen the connections of the other components of the course (laboratories, lectures, tutorials) and in so doing, facilitate students’ problem-solving skills in the laboratory and tutorials. Focus group sessions have been scheduled to obtain further in-depth feedback from the students to investigate how to explicitly facilitate these connections and to address the weaknesses and strengths of the e-poster project.

Outcomes

Changes in the nature of MICR2201 following the introduction of the progressive e-poster were marked by the transformation of the tutorial groups into collaborative learning communities. In comparison to the previous two years, the quality of discussions in WebCT was indicative of higher levels of thinking, integration of theory and practice, and a culture of peer learning and teaching. Indeed this was one of the strongest elements of evidence demonstrating the evolution of students’ intrinsic motivation with this assessment. The natural integration of theory and concept with practical application into the context of the research project can be witnessed in the e-posters (see link to sample poster below). Peer learning and teaching, as well as mentorship within the e-poster discussions, were also apparent. The e-poster functioned as an assessable component that structured the step-by-step processes of transfer and application, to make them ‘visible’ to the learner. As the tutorial groups evolved into learning communities, the discussions in WebCT revealed the students’ own metacognitive realisation of the utilisation of the e-poster assessment for learning, rather than of learning: student post in WebCT:

We should use version 3 of the poster as a learning tool and really focus on bringing it together conceptually. I would even suggest that we have a meeting (in a relaxed atmosphere) where we talk about anything that we are still confused about and help each other sort things out... I think this could be a really good revision that will make the poster even better and of course help us with the final...

The e-poster assessed student engagement in the process of inquiry, and facilitated review and reflection throughout the course (rather than at the end). For the instructor, this assessment approach progressively mapped group learning of the experimental, conceptual, and collaborative processes. Detailed rubrics were developed (see Appendix 2) to assess each version of the e-poster to ensure alignment with learning goals and consistency of assessment across all 22 teams. The rubrics were also distributed to the students to provide transparency of process. Our goal was to strengthen student engagement through contextual relevance in a process of inquiry that mirrors professional practice, and align the pedagogy of the discipline to the practice of the discipline. The iterative model of inquiry and learning promoted through the e-poster is relevant not only to undergraduate and postgraduate courses, but serves as a mentorship model for research supervisors.

The e-poster primarily encouraged students to work collaboratively and to learn from their peers. As a formative assessment approach, the students also recognised the e-poster as a learning tool.

One of the goals in this course is to foster students’ metacognitive awareness; i.e., thinking about their learning. The responses from the survey indicate that this desired outcome was not entirely achieved. Our interpretation is that the focus on group collaboration may have precluded individual introspection. In addition, students did not believe that the e-poster facilitated their problem-solving skills. We had initially assumed the e-poster would strengthen the connections of the other components of the course (laboratories, lectures, tutorials) and in so doing, facilitate students’ problem-solving skills in the laboratory and tutorials. Focus group sessions have been scheduled to obtain further in-depth feedback from the students to investigate how to explicitly facilitate these connections and to address the weaknesses and strengths of the e-poster project.

Changes in the nature of MICR2201 following the introduction of the progressive e-poster were marked by the transformation of the tutorial groups into collaborative learning communities. In comparison to the previous two years, the quality of discussions in WebCT was indicative of higher levels of thinking, integration of theory and practice, and a culture of peer learning and teaching. Indeed this was one of the strongest elements of evidence demonstrating the evolution of students’ intrinsic motivation with this assessment. The natural integration of theory and concept with practical application into the context of the research project can be witnessed in the e-posters (see link to sample poster below). Peer learning and teaching, as well as mentorship within the e-poster discussions, were also apparent. The e-poster functioned as an assessable component that structured the step-by-step processes of transfer and application, to make them ‘visible’ to the learner. As the tutorial groups evolved into learning communities, the discussions in WebCT revealed the students’ own metacognitive realisation of the utilisation of the e-poster assessment for learning, rather than of learning: student post in WebCT:

We should use version 3 of the poster as a learning tool and really focus on bringing it together conceptually. I would even suggest that we have a meeting (in a relaxed atmosphere) where we talk about anything that we are still confused about and help each other sort things out... I think this could be a really good revision that will make the poster even better and of course help us with the final...

The e-poster assessed student engagement in the process of inquiry, and facilitated review and reflection throughout the course (rather than at the end). For the instructor, this assessment approach progressively mapped group learning of the experimental, conceptual, and collaborative processes. Detailed rubrics were developed (see Appendix 2) to assess each version of the e-poster to ensure alignment with learning goals and consistency of assessment across all 22 teams. The rubrics were also distributed to the students to provide transparency of process. Our goal was to strengthen student engagement through contextual relevance in a process of inquiry that mirrors professional practice, and align the pedagogy of the discipline to the practice of the discipline. The iterative model of inquiry and learning promoted through the e-poster is relevant not only to undergraduate and postgraduate courses, but serves as a mentorship model for research supervisors.
Future work

The WebCT discussion postings (>15,000) and e-posters together represent a significant resource for analysing the students’ cognitive and affective learning. We and others have found detailed analysis of online postings to be valuable in determining whether and how student learning is enhanced through specific contexts (Hazel et al. 1996; Takayama 2005; Treleaven 2003). We are in the process of developing specific rubrics for the analysis of: i) the WebCT postings, ii) the e-posters, and iii) the focus group interviews in order to identify the specific ways in which students have learned about the scientific inquiry process and the specific areas that need to be strengthened.

The following excerpt from one group’s final e-poster provides anecdotal evidence that we are moving in the right direction; it is our goal to continue improving our model.

...We have gained an unbelievably in-depth understanding of the methodology involved from strategic planning, constant modification, and the execution of procedures. The need to adopt a flexible experimental protocol was realised at an early stage of the investigation to accommodate further structural changes ... What we have learned from other groups has been undeniably valuable for our own improvements. Our group has grown to learn tremendously from each other as a result of compromisingly high standards for ourselves and our own improvements. Our group has grown to realise the significance of team work in overcoming difficult challenges, both in the laboratory, and in the collaboration on the E-posters. We set uncompromisingly high standards for ourselves and this is reflected in our commitment and enthusiasm to this investigation. While there is some disagreement between group members in differing perspectives and ideologies, we believe that we have learned tremendously from each other as a result of the dynamics and the interactivity of the group over the course of this insightful experience. The camaraderie and sharing of knowledge gained are characteristics of our group, which we value highly.

Acknowledgements

We wish to acknowledge the invaluable efforts of the course tutors in their facilitation of the e-poster projects. The e-poster platform was kindly provided by the Knowledge Media Lab of the Carnegie Foundation for the Advancement of Teaching.

**Isolation and Identification of**

### What is the aim of your investigation?

- Briefly outline the plan and projected timeline of your group's approach and process for isolation and identification. Identify any steps or outcomes you are unsure of, and how you might seek guidance in clarifying those areas of uncertainty.

### What resources/references have you found so far that might aid you in your investigation?

- What questions (if any) do you have about the work described in this resource material? What information in these resources has been relevant to your group discussion so far?

### What will your group's initial approach to this investigation be?

- From whom will you collect your samples for isolation? How will you collect your samples? What are the characteristics of your organism, upon which you have based these decisions? What other organisms might be present in the environmental niche you have chosen?

### What other questions or concerns does your group have at this time?

- What other questions or concerns does your group have at this time?

### What will you do next to address these questions/concerns?

- What will you do next to address these questions/concerns?
Appendix 2:

MICR2201 2005
Assessment guidelines for e-poster v.1

General comments:
• Students must demonstrate correct usage of terminology.
• Genus and species names must be italicised.
• Spelling and grammatical errors will be penalised.
• Posters should reflect collaborative effort. For example, rather than state: “I have found the following resources…”, students should state: “We have found the following resources…”
• Individual contributions will be taken into account. Those that have not participated toward the research, development of approaches, synthesis of ideas, etc. in the WebCT e-poster discussion forum for their group will receive no marks. Tutors will analyse the contribution of group members through WebCT logs, tutorial discussion minutes, chatroom logs, and any other relevant and approved sources for evidence of student contributions.

1. What is the aim of your investigation? (3 pts)
Clear definition of research question in no more than 1 - 2 sentences. The aim should include the following:
• Isolation of the genus __________
• Source of sample
• Simple statement of approach

2. What resources/references have you found so far that might aid you in your investigation? What question(s) do you have about the work described in this resource material? What information in these resources have been relevant to your group discussion so far? (8 pts)
Thorough coverage and interpretation of literature including:
• Utilisation of appropriate, peer-reviewed research material (2 pts)
• Proper formatting of reference material, including images. (2 pts)
• Relevance to the research aim and the current stage of the group work. If certain references have been collected with the intent of application toward the next step or possible future approaches, this should be specified and explained. (2 pts)
• Simply listing references is not sufficient. Groups must demonstrate that they have read the material and how it relates to their work. If they did not understand certain parts of the article, this is perfectly okay – however, they must indicate this and perhaps refer to this fact in the answer to question 6. (2 pts)

3. What will be your group's initial approach in this investigation? (8 pts)
• This section does not need to be exhaustively long-remember, it is an initial approach. We are not looking for a complete experimental protocol.
• The rationale for the initial approach should be stated, and should be based on the characteristics of the organism. (4 pts)
• The initial approach can also include the process the group has been going through to research the organism and learn about various selective and differential media. (4 pts)

4. Briefly outline a plan and predicted timeline of your group’s approach and process for your isolation and identification. Identify any steps or topics you are unsure of, and how you might seek guidance in clarifying these areas of uncertainty. (8 pts)
• Logical, step-wise outline.
• If the group is unsure of certain areas, they should be highlighted and the group should state what they are unsure of. The group should propose how they will go about seeking guidance in clarifying these areas of uncertainty.
• The plan is not meant to be complete and perfect at this stage. We are looking for thoughtful reflection, and identification of those areas you need help in.

5. From where will you collect your samples for isolation? How will you collect your samples? What are the characteristics of your organism upon which you have based these decisions? What other organisms might be present in the environmental niche you have chosen? (8 pts)
• Sound rationale with regard to source of sample. This should be explained in the context of the characteristics of organism, including physical and nutritional growth requirements. (4 pts)
• Proper handling procedures and safety precautions for sample collection. (2 pts)
Discussion of what other genera might be present in this environment, and what characteristics they share with your genera. (2 pts)

6. What other questions or concerns does your group have at this time? (5 pts)

Questions and issues should demonstrate relevance to the proposed approach and what you know about your organism so far. Issues are not limited to scientific questions; i.e., your group may have concerns regarding the collaboration, or perhaps queries about how to present your work, find out further information, track down a source of information... perhaps even technical issues. This question is meant to help you sort out what you might be having problems with, or what you need to figure out.

7. What will you do next to address these questions/concerns? (5 pts)

The group needs to collaboratively agree on what they need to do to address their answer to question 6. For example, if they need to find resources on a specific topic, it is not sufficient to simply state they will do a web literature search or go to the library. They should identify what criteria they would use to determine suitable resources. If the concern has to do with the working dynamics of the group, the group should collaboratively think of approaches to address this issue.
What new ideas about your organism or your investigation has your group developed from your work on the first e-poster? What process(es) is your group focusing on at this stage of your investigation? What do you need to do next? (8 pts)

- Ideas should be based on sound demonstration of understanding of the morphological, metabolic, and/or physiological characteristics of the organism in relation to your experimental observations so far. If you identified problems/misunderstandings/incorrect application of laboratory procedures from your first e-poster, point these out and explain how you came to this conclusion. If you discovered an interesting or unexpected observation, describe why they are interesting or unexpected based on your group’s conceptual understanding of the characteristics of your organism. These suggestions are not exhaustive; this section requires thoughtful group reflection and review.
- Justify your rationale with regard to what process you are focusing on, and what needs to happen next. Use criteria described above.

Briefly map your group’s progress thus far in your isolation and identification. Identify any steps or outcomes you are unsure of. How will you proceed to clarify these areas of uncertainty? (8 pts)

- Logical, step-wise outline identifying specific procedures/media used/biochemical tests, etc thus far.
- If you mention the use of selective/differential media, or a specific biochemical test, you must demonstrate your understanding of the basis of this biochemical test or medium. What is happening with your bug? What about other bugs that might be present in the sample?
- Outcomes and observations at each stage so far should be briefly described.
- Controversial or confusing outcomes should be noted (or if an experiment ‘didn’t work’, what is your explanation in retrospect?). Specific areas of uncertainty should be highlighted and the group should clearly explain what it is that they are unsure of.
- The group should propose how they will clarify areas of uncertainty.

Read AT LEAST two other e-posters from the FMI e-poster site. What conceptual links can you make to your organism or genus based on what you have learned from the other posters? Please make sure you specify the poster group number when referring to information gathered from the other posters. (8 pts)

- Demonstration of sound understanding of the metabolic, physiological and/or morphological characteristics of your organism with respect to your comments on the other poster (whether you are comparing to a poster with the same or different genus).
- Discussion should be RELEVANT TO YOUR ISOLATION PROJECT. Comparisons about specific characteristics or experimental outcomes should demonstrate your conceptual understanding.

What characteristics have you identified and established with regard to your sample so far? What tests and/or experiments do you need to do next? Why? (4 pts)

- Demonstration of sound understanding of the metabolic, physiological and/or morphological characteristics of their organism.
- This section should be consistent with questions 3 and 4.

What other questions or concerns does your group have at this time? What will you do next to address these questions/concerns? (5 pts)

- The guidelines for this section have been provided in the guidelines for e-poster 1. In addition, if there were any issues identified in e-poster 1 that still remain to be resolved, they should be indicated here.

Other assessment criteria:

Consistency of all e-poster sections (5 pts): Is the e-poster consistent across all sections? Conflicting statements or too much repetition will be penalised. It is imperative that all group members have checked through all sections and collaborative agreement has been reached. It is also imperative that every group member understands the “whole” picture with regard to theoretical and experimental aspects of this research project.

Organisation and Communication (4 pts): Has the group demonstrated an organised, strategic approach to their collaborative work as evidenced by WebCT discussions? Do members of the group communicate clearly and decisively to each other, and with the tutor? Are tutorial minutes presented clearly and comprehensively? Are there spelling or grammatical errors? Are there errors in the use of terminology?
**CAL-laborate, August 2006**

**Individual contribution toward group (50 pts):** This will be weighted based on the quality AND quantity of contributions you have made toward your group work in WebCT, the tutorial minutes, tutorial attendance and participation, and other records of participation (chatroom logs; minutes of face-to-face meetings with your group).
