Published on 30 May 2014 at http://escholarship.library.usyd.edu.au/journals/index.php/LIN

The invertebrate fauna known from within the caves at Jenolan is inventoried and summarised. At least 136 individual taxa have been identified although less than one-half (43%) are assigned to described species, the rest are either undescribed (8%) or have only been identified to genus level (31%) or higher taxa (18%). The collected fauna is dominated by arachnids (47%) and collembolans (24%) followed by insects (15%) and crustaceans (6%) with three or fewer taxa identified in each of the remaining groups comprising molluscs, diplopods, chilopods, annelids, platyhelminths and nematodes. In terms of ecological dependence on caves, 53% of collected taxa comprised typically epigean species with the remainder considered to be habitual cave-dwellers. Eight species (revised from 14 previously) are considered to be obligate hypogean species (terrestrial troglobites or aquatic stygobites) comprising three species of springtail, two spiders, a pseudoscorpion and two aquatic crustaceans. The diversity of troglobite species is fairly typical for karst areas in the eastern highlands of NSW but higher unrecorded diversity of stygobite species is predicted.

While the invertebrate cave fauna of Jenolan has received more attention from biologists than any other karst area in NSW, substantial knowledge gaps remain. Research and conservation priorities are: (1) identify existing collections and describe new species, focussing on troglomorphic taxa which are likely to be locally endemic and of conservation significance; (2) targeted field surveys for rare troglomorphic taxa which are under-represented in existing collections; (3) sample for aquatic micro-crustacea and other stygofauna in vadose zone, phreatic zone and interstitial habitats; (4) sample for troglobites in meso-cavern and other cryptic terrestrial habitats.

Manuscript received 23 October 2013, accepted for publication 11 December 2013.

KEYWORDS: cave fauna, Jenolan, stygobite, troglobite

INTRODUCTION

The purpose of this paper is fourfold: (1) to provide an historical inventory of the invertebrate cave fauna recorded from the Jenolan karst, which to date, has largely existed in unpublished reports; (2) to summarise the current state of taxonomic and collection knowledge; (3) to identify knowledge gaps and priorities for further research and conservation; (4) to briefly re-assess the significance of the Jenolan cave fauna in a regional and national context.

The Jenolan Caves have attracted the attention of European scientists since first being visited in the 1830s, however little attention was paid to the invertebrate fauna, either above or below ground, until guide Joseph C. Wiburd initiated collections from the 1880s until around 1903. Many of Wiburd’s specimens are in the Australian Museum collections. Most specimens appear to be surface collections although two species of cave-dwelling spider (Cycloctenus abyssinus and Laetesia weburdi) described by Urquhart (1890), are historically important, being the first cave dwelling invertebrates described from New South Wales.

After Wiburd and Urquhart’s pioneering efforts, further documentation of Jenolan’s invertebrate cave fauna lapsed until the 1960s when collections were reinitiated by John Polessen, Barbara Dew, Elery Hamilton-Smith, Ted Lane and Aola Richards. Their efforts identified ten named species of spider, pseudoscorpion, harvestman, springtail and beetle, plus several other unidentified species of millipede, cricket and moth (Hamilton-Smith 1967).

The next era of systematic survey occurred
between 1986 and 1988, when Michael Gibian, Louise Wheeler and Graeme Smith, with further involvement from Mike Gray, Glenn Hunt, Penelope Greenslade, Mia Thurgate and Ernst Holland, sampled the fauna by hand as well as netting streams and taking samples of leaf litter and guano for Tullgren funnel extractions. These efforts increased the number of recorded taxa (most undescribed) from 26 to 67 including Jenolan’s first troglobitic spiders and aquatic cave fauna (Gibian et al. 1988).

Systematic collection efforts were continued by Eberhard (1993) with emphasis on aquatic macrofauna and interstitial habitats using baits, nets and pumping methods. These collections and other previous accessible records were part of a wider survey of New South Wales cave fauna which established Jenolan as one of the better sampled karsts in the State and possessing a comparatively rich invertebrate cave fauna (Eberhard and Spate 1995). Since this last survey and inventory at Jenolan, which remains unpublished in the scientific literature, further field collection efforts have been very limited.

As is typical of invertebrate surveys, and subterranean fauna especially, the taxonomic (Linnaean) shortfall means that much of the Jenolan material remains incompletely identified, awaiting specialist attention. Some progress has however been made with descriptions of four mite species (Halliday 2001), one spider (Forster et al. 1987), one amphipod (Bradbury and Williams 1997), redescription of the Jenolan harvestman (Hunt 1992), and further identification of springtails (Greenslade 2011); descriptions of an additional four mite species are in preparation (Halliday in litt. 2013).

The survey and inventory by Eberhard and Spate (1995) informed the stance taken in a subsequent paper by Thurgate et al. (2001a) who applied the metaphor ‘from rags to riches’ to highlight subterranean biodiversity in New South Wales and ‘dispel former erroneous perceptions of a depauperate fauna’. Since this paper was published, a great amount of field survey and taxonomic research has been undertaken in other states, mostly in Western Australia and South Australia (Eberhard et al. 2009; Guzik et al. 2011), the results of which reinforce the need and timeliness for formal documentation and reappraisal of Jenolan’s cave fauna as presented herein.

DEFINITIONS

Biospeleologists classify subterranean species according to their degree of ecological association and dependence upon subterranean environments. Frequently this association is presumed or inferred, especially in the case of obligate subterranean forms, on the basis of morphological modifications, typically a reduction or loss of pigmentation and eyes, elongation of appendages and compensatory enhancement of non-optic sensory structures.

Accidentals: Typically surface dwelling species whose occurrence underground is incidental, having ‘accidently’ wandered or fallen in, or been carried underground by sinking water (e.g. flood), gravity or air currents

Epigean: Surface dwelling

Hypogean: Subterranean

Guanophile/Guanobite: Species that are associated with the guano of cave roosting bats or birds. Species associations with guano may be facultative (guanophile) or obligate (guanobite).

Meso-cavern: Subsurface cavity generally too small for a human to enter. Underground voids in the size range 0.1-20 cm, especially in karst and volcanic substrates. cf. macro-cavern which are voids > 20 cm, especially caves large enough for human entry.

Stygophile/Stygobite: Terms equivalent to troglobite and troglobite for aquatic cave fauna

Trogloxene: Species that habitually occupy caves for a part of their life cycle but frequently return to the surface for food. e.g. bats and cave crickets.

Troglophile: Species that can complete their whole life cycle in hypogean environments but populations of the same species also occur in epigean environments. They usually do not possess typical morphological modifications, but in some cases the cave-dwelling populations may show some degree of modification (e.g. lighter pigmentation or reduced eye size) compared to their surface-dwelling conspecifics.

Troglobite: Species that are obligate cave dwellers and entirely restricted to the subterranean environment and showing typical troglomorphic traits (see next).

Troglophylomorph: Any morphological, physiological, or behavioural feature that characterizes subterranean fauna. Common morphological traits include: reduction of eyes, pigment, wings; elongation of appendages; specialization of non-optic sensory structures.
OVERVIEW

An overview of the systematic composition and current state of taxonomic knowledge appears in Fig. 1 and Table 1 and a more comprehensive list of the faunal records and the location of specimens is in the appendix. At least 136 individual taxa have so far been collected within the caves at Jenolan. In terms of recorded diversity, the collected invertebrate fauna is dominated by arachnids (47%) and collembolans (24%) followed by insects (15%) and crustaceans (6%) with three or fewer taxa identified in each of the remaining groups comprising molluscs, diplopods, chilopods, annelids, platyhelminths and nematodes (Fig. 1).

Springtails (Collembola) were very abundant and diverse with 33 recognised taxa including three troglobites and seven undescribed species (Table 1). Although a naturally diverse group, their disproportionate representation in Jenolan cave collections partly reflects the survey and identification efforts applied to this group by Greenslade (2002) and which contrasts with most of the insect groups excepting the beetles (Coleoptera) which are reasonably well known. The arachnid collections are dominated by terrestrial mites (Acarina) and spiders (Araneae) with 28 and 31 recognised taxa respectively. This also partly reflects the survey and identification efforts for these groups applied by Halliday (2001) and Gray (1973) respectively. While eight crustacean taxa have been recorded to date, this is likely to under-represent the actual diversity because this group is typically diverse in karst groundwater. Moreover, Jenolan’s deep groundwater habitats have been poorly sampled for aquatic micro-crustacea. In terms of taxonomic resolution, less than one-half (59 species, 43%) of the 136 taxa are currently assigned to described species, the rest are either undescribed (11 species, 8%) or have only been identified to genus level (42 taxa, 31%) or higher (24 taxa, 18%) (Table 1).

A systematic list of all invertebrate taxa recorded from inside caves at Jenolan is given in the appendix. In terms of ecological classification, many of the taxa are considered to be ‘accidental’ or incidental hypogean fauna (72 taxa), falling into caves or being washed in by flood events. Forty-nine (49) taxa are considered to be troglophiles (or stygophiles). Only

![Figure 1. Systematic composition of Jenolan invertebrate cave fauna collections showing the number of taxa identified in major taxonomic groups.](image-url)
eight species are considered to be troglobites or stygobites, comprising three species of springtail, two spiders, a pseudoscorpion, and two crustaceans (Table 1, Figs 2, 3 and 4).

### DETAILED SYSTEMATIC ACCOUNT WITH NOTES ON COLLECTIONS AND ECOLOGY

**ENTOGNATHA**

**Subclass Collembola**

Penelope Greenslade has tentatively identified 33 taxa from 11 families from material predominantly collected by Gibian, Smith, Wheeler, and Eberhard (Greenslade 2002). Collembola were mainly collected by hand from the surface of pools, from rock walls, stalagmites and other surfaces, but some Tullgren funnel extractions were taken of guano and flood debris, and some pitfall traps baited with arthropod remains. Collembola were observed to be very abundant on moist surfaces (e.g. stalagmites) in the humid and dark sections of caves developed for tourism (e.g. Orient Cave upper levels) (S. Eberhard personal observation, 1993). It is hypothesised that tourism activities have altered the ecology of these otherwise normally dark and energy-poor deep zone environments, via the introduction of artificial light and nutrients with associated growth of fungi and lampen-flora which provide a food source for grazing invertebrates to colonise deep zone habitats that would normally preclude them.

The most abundant species (*Onychiurus sp. fimetarius* group, *Ceratophysella* spp. *Mesophorura sp. krausbaueri* group and *Folsomia candida* (Willem, 1902)) also occur in Europe and are almost certainly introduced to Australia. The undescribed native *Adelphoderia* sp. was the most frequently occurring
Figure 2 (left). Scanning electron micrograph of *Adelphoderia* sp., < 1 mm (Penelope Greenslade)

Figure 3 (below). Examples of Jenolan cave fauna, approximate length (including legs) indicated (photographer). a. *Cavernotettix* cave cricket, 25 mm (Stefan Eberhard); b. *Badumna socialis* 16 mm (Mike Gray); c. *Stiphidion facetum* (with dipteran prey), 25 mm (Stefan Eberhard); d. Web of *S. facetum* (Helen Smith); e. *Laetesia weburdi*, 5 mm (Mike Gray); f. *Holonuncia* cave harvestman, 20 mm (Stefan Eberhard).
Figure 4. Examples of Jenolan cave fauna. a. *Trechimorphus diemenensis*, 5 mm; b. Pseudoscorpion *Sathrochthonius tuena*, 1.4 mm; c. Troglobitic pseudoscorpion *Pseudotyrrannochthonius jonesi*, 3 mm; d. *Icona* sp., 8 mm, a troglobile with pigment and eyes; e. Troglobitic Theridiidae sp. (previously as *Icona* sp. 3), 3mm; f. Stygobitic amphipod *Neocrypa simoni*, 4 mm; g. Stygobitic crustacean, Psammaspididae gen. et sp. nov. 5mm (a.- f. Mike Gray; g. Peter Serov).
species (Fig. 2). Almost half the number of taxa were recorded only once or twice, mostly from extractions of flood debris and are almost certainly ‘accidentals’ washed in by flood waters. The Jenolan fauna was found to contain a greater number of genera with exotic species compared with the Tasmanian cave fauna (Greenslade 2002).

Greenslade considered that four of the Jenolan species were likely troglobites and another 10 species probable troglophiles. The troglobitic species of most interest from conservation and phylogenetic points of view (Kenyura sp.) is known, to date, only from a single cave. With the exception of Coecobrya communis (Chen and Christensen 1997) (an exotic introduced species previously incorrectly identified as Lepidosinella armata), none of these species has yet been described. Coecobrya communis was later reported by Chen et al (2005) to also occur in worm beds and is therefore considered in this work as a troglophile rather than a troglobite. Within the Jenolan Caves it has been collected from drains and gutters and on stalagmite.

All troglobitic Collembola, except Adelphoderia sp., were rare in the collections. Kenyura sp. was collected from mud banks and the surface of muddy pools; Oncopodura sp. from stalagmite, the surface of pools and from mud banks and Arthropalites sp. from guano, although it may also be an exotic introduction (Greenslade in litt.). Adelphoderia sp. has been taken from stalagmite, the surface of pools, mud banks, flowstone, fungi, guano (1 record) and pitfall (one record). It was first collected by Hamilton-Smith around 1964 and was still present in 1988 surveys despite living in areas which are regularly cleaned and subject to high tourist visitation. It may be parthenogenetic as no males have been collected.

Greenslade considered the troglobitic species as the most important from a conservation standpoint and the collection sites of most importance as Mammoth, Orient and Imperial Caves (albeit probably biased by relative collecting effort).

INSECTA

Specimens belonging to the Blattodea, Orthoptera, Diptera, Lepidoptera, Hymenoptera and Psocoptera were deposited in the Entomology collections of the Australian Museum, however they do not appear to have been registered in the museum data base.

Order Coleoptera

At least seven beetle taxa belonging to four families were collected from caves. The carabid beetles were examined by Dr Barry Moore (then CSIRO) who identified three species, the most common being Trechimorphus diemenensis (Bates, 1878) (Fig. 4a). This species is widespread in southeast Australia, however cave forms possess shorter wings than surface forms (Moore 1964). The second species (Meonis convexus Sloane, 1900) has also been found in the nearby Tuglow Caves and is possibly troglophile. The third species Prosopogmus namoyensis Sloane, 1895 is considered to be accidental. The pselaphid beetle Tyromorphus speciosus (King, 1865) was recorded by Hamilton-Smith (1966) from the Southern Limestone at Jenolan (and from caves in Victoria and Queensland). Several other pselaphids were collected by Gibian et al. (1988) which probably belong to this species, but this has not yet been confirmed. The introduced ptinine ‘spider’ beetle Pitinus exulans Erichson, 1842 has been reported from Jenolan (Hamilton-Smith 1967) as well as many other caves in most Australian states. The staphylinid beetle Myotyphlus jansoni (Matthews, 1878) was also reported by Hamilton-Smith (1967) in association with bat guano.

Other unidentified beetles or their larvae have been collected in Imperial, Mammoth, McKeowns Hole, Devil’s Coach House and Hennings Cave.

Order Orthoptera

Cave crickets (Cavernotettix sp.) are commonly encountered trogloxenes in the entrance, twilight and transition zones of caves (Fig. 3a). The species from Jenolan is closely related to those from other karsts in the region but remains undescribed.

Order Hemiptera

Dr Lionel Hill examined the material collected, noting some root feeding Coccoidea, one lygaeid nymph and two species of the dipsocoroid genus Ceratocombus. One may be C. australiensis Gross, 1950 but the other is undescribed. Both also occur on leaf litter in epigean habitats and are therefore regarded as troglophiles.

Order Diptera

Diptera collected or reported include sciarids (Chaetosciara sp. and Corynoptera sp.), tipulids and chironomids. They have not been identified and all are considered to be accidental or trogloxenes.

Order Lepidoptera

The guanophilic tineid moths Monopis crocicapitella (Clemens, 1859) and Hofmannophila pseudospretella (Stainton, 1849) have been reported from within the caves associated with bat guano. Hamilton-Smith (1967) reported that Monopis sp.
moths have been “found in almost all bat-inhabited
caves of eastern Australia, where the larvae develop
on heaps of guano”. Both species of moth are
cosmopolitan.

Order Hymenoptera
Ants collected in Hennings and Mammoth Caves
remain unidentified.

Order Psocoptera
Booklice have been collected from detritus and
guano in Mammoth, McKeowns Hole and Arch Caves.
One cosmopolitan psocid (Psyllipsocus ramburii
Selys-Longchamps, 1872) has been reported from
many caves in Australia (Smithers 1964) as well as
other situations and is considered to be a troglobile.
The Jenolan material has not yet been identified.

ARACHNIDA

Order Acarina
Numerous mites belonging to four orders were
collected both in and around the caves at Jenolan by
Gibian et al., Eberhard and Holm. At least twenty-
three mesostigmatid taxa (including Uropodina)
were collected within the caves either in leaf litter
accumulations or bat guano. Dr Bruce Halliday
(2001) has published his findings on the Jenolan
Mesostigmata (excluding Uropodina) and has
provided preliminary information on a paper currently
in preparation on the Uropodina. A single parasitic
tick extracted from guano in Paradox Cave has been
identified (considered to be a reptile parasite) but the
remaining Jenolan mite fauna has not been further
examined. This includes mites from three families
of the suborder Prostigmata found in low numbers
in various caves. Oribatids were present in most
samples and were sometimes abundant. No work has
been done on these two suborders at Jenolan.

Most of the mites collected are also known from
surface habitats. Four species have been described
from the Jenolan cave material (Halliday 2001) and
descriptions of a further four Uropodina species
are pending (Halliday in litt. 2013). None of the
mites described displayed morphology associated
with adaptations to subterranean life. We have
tentatively classified about half of the recorded taxa
with adaptations to subterranean life. We have
tentatively placed in the genus
Laetesia, otherwise only
misspelt by Urquhart).

Order Araneae
Spiders are the most commonly seen arachnids in
surface and cave habitats at Jenolan. The best known
species is the troglobilic ‘social spider’, Badumna
socialis (Rainbow, 1905) (Desidae, Fig. 3b), whose
sheet webs are common on the roof and walls of Jenolan’s Grand Arch through which the road passes.
Their web density can be so great that individual
webs merge to form a single large sheet, punctured
by the entrance holes of each spider. Clumps of web
periodically fall off the roof, and it was suggested
that dust and chemical pollution from vehicles might
be adversely affecting the population (James et al.
1990). While it was found that the webs were highly
polluted by lead from vehicle exhaust fumes (Hose
et al. 2002), direct effects on the spider population
were not demonstrated, but continuing monitoring of
the arch population was recommended. The species
is also found in arch habitats at Colong, Abercrombie
and Wombeyan. Few are seen in caves beyond the
cave arch and entrance regions, where local air
currents (and night lighting) probably bring in a
steady supply of insect food. The genetic relationships
between the different arch populations, and a close
surface relative, Badumna longingua (Koch, 1867)
need testing to properly assess their taxonomic and
conservation status. A limited protein electrophoretic
study (Gray, unpublished) showed phylogeographic
differentiation between the Jenolan and Wombeyan
populations. Stiphidion facetum Simon, 1902, a
widely distributed surface species, is also commonly
seen in hammock-like sheet webs on the walls of the
Grand Arch (Figs 3c and 3d).

The first spider described from Jenolan Caves
was the troglobilic linyphiid, Laetesia weburdi
named for the Head Guide, Joseph Wiburd (name
misspelt by Urquhart). Laetesia weburdi (Fig. 3e) is a
relatively small spider with slender legs and variable
pigmentation (dark to pale). It is found in small sheet
webs suspended from walls and formation. The
species was originally placed in genus Linyphia, but
in reassigning this species to Laetesia, van Helsdingen
(1972) noted its close similarity to species from cave
and surface habitats in south west Australia, notably,
L. mollita Simon, 1908 (the type species of the
genus). A second linyphiid, as yet undescribed, is a
troglobitic species, lacking both pigment and eyes.
It is smaller and much rarer than L. weburdi and is
known only from one male (in poor condition) and
juveniles. The webs are similar to those of L. weburdi
and were associated with moist formation in Imperial
and River Caves. Recent searching has so far failed
to find the additional material necessary to properly
describe the species.

An interesting group of theridiid spiders are
tentatively placed in the genus Icona, otherwise only
known from the subantarctic islands of New Zealand
(Forster 1955a and 1964). They were originally
placed in *Steatoda* (in Gray 1973), and subsequently reassigned to ‘in or near’ *Icona* following examination by H.W. Levi (pers. comm.). These spiders, currently undescribed, are distributed across southern Australia as troglophilic and troglobitic species. At Jenolan there is at least one unidentified species of this group (Fig. 4d), a relatively uncommon troglobite with varying degrees of depigmentation (it was at first thought to represent two species). These troglobites were described as having “scatty webs over mud or leaf litter deposits” (Gibian et al. 1988).

A small troglobitic species of theridiid from Hennings Cave (Fig. 4e) was also previously included under *Icona* (in Gibian et al. 1988, Eberhard and Spate 1995). The taxonomic placement of this eyeless and totally depigmented species must wait until adult specimens are available.

A troglophilic species of *Cryptachaea* is widely distributed in south-eastern Australia: *C. gigantipes* (Keyserling, 1890) is recorded from a number of NSW caves (Smith et al. 2012), including Jenolan (previously as *Achaearanea verruculata* (Urquhart, 1885) in Gibian et al. 1988, Eberhard and Spate 1995). This large species makes a typical theridiid ‘gumfoot’ capture web.

Like the linyphiids, the other web building troglobites are very small. These include members of two surface litter dwelling families: Micropholcommatidae (0.5-1.5 mm) spiders found on mud banks, in litter debris and in small webs on stalagmites; Mysmenidae (up to 2 mm) where a male was taken from a ‘small web’. On close examination these webs are usually seen to be modified orb webs.

Small theridiosomatid spiders (*Baalzebub* sp.) are often seen in cave entrance, twilight and transition zones in their distinctive cone-shaped orb webs. These spiders use a central tension line to maintain this web shape; they release the tension when prey approaches allowing the sticky orb web to rebound over it.

The non web-building spider fauna includes several vagrant troglophilic hunters often associated with loose rock, soil bank, guano deposit, litter detritus and root mass habitats. Most belong to genera endemic to Australia and New Zealand. *Cycloctenus abyssinus* (family Cycloctenidae) has been periodically recorded in cave habitats. The original description (by Urquhart 1890) was of a female and subadult males; Rainbow (1893) described an adult male and referred to several female specimens, but the whereabouts of these are unknown, and today there are no pre-1900 specimens or males currently recorded in the Australian Museum collections. These spiders are well pigmented and have large eyes and are probably conspecific with a surface species. The spiders are not often seen, but are probably an important predator in the caves ecosystem.

*Kaiya terama* Gray, 1987 (Gradungulidae) has been found in several caves at Jenolan, and is a common epigean log and litter dwelling species.

*Tasmanoonops* spp. (Orsoldiidae) are much smaller spiders that are found in similar surface habitats. They have been collected in Elder and Hennings caves associated with moist habitats, including hanging root masses.

**Order Opiliones**

One troglophilic species, the triaenonychid *Holomuncia cavernicola* (Fig. 3f) was originally described from ‘Jenolan Caves’ (Forster 1955b) and re-described by Hunt (1992) based on the holotype and additional material collected by Gibian et al. (1988), Hunt and others. While the species regularly occurs in caves at Jenolan, specimens are also found in epigean habitats. The harvestman in caves at Tuglow is tentatively assigned to *H. cavernicola*. Other species in the genus *Holomuncia* are found within multiple karsts in southern New South Wales. Pigmentation and eye size varied between cave and surface populations but also within cave populations (Hunt 1992).

A second species of harvestman, the neopilionid *Megalopsalis* sp. is known from two specimens collected from the entrance chamber of Mammoth Cave and is probably accidental in caves.

**Order Pseudoscorpiones**

Three species have been collected at Jenolan. One is probably an accidental; the other two were described by Chamberlin (1962) with only vague locality data but have since been confirmed to occur at Jenolan. *Sathrochthonius tuna* (Fig. 4b) is a guanophile from Bow and Paradox Caves as well as from Wombeyan Caves. The other is a troglobite, *Pseudotyrannochthonius jonesi* (Fig. 4c) known from Imperial Cave and the Chevalier extension.

**MYRIAPODA**

**Order Geophilomorpha**

A geophilomorph centipede seen on flowstone in Hennings may be an accidental.

**Order Polydesmida**

Polydesmid millipedes collected from several caves are considered to be troglobilithes. No further work has been carried out.
INVERTEBRATE CAVE FAUNA OF JENOLAN

CRUSTACEA

Gibian et al. (1988) recorded the first aquatic cave fauna from Jenolan, reporting amphipods (Crangonyctidae), copepods (Harpacticoida, Cyclopoida) and ostracods. This material, augmented by the more extensive collections of Eberhard (1993), has been re-examined and some identifications amended to at least six aquatic taxa.

Order Cyclopoida
At least two, possibly three, species of copepod have been collected in Mammoth and Lucas caves. The two species that have been identified are well known surface copepods and may be accidentals or stygophiles. The third putative species remains unidentified.

Order Isopoda
Two species of terrestrial oniscid slaters have been collected, one strongly pigmented and eyed from Elder Cave, the other is a single weakly pigmented specimen (Styloniscus sp.) from Mammoth Cave. We have been unable to locate the Elder Cave specimen and the Styloniscus specimen has not been further studied.

One species of aquatic phreatoicoid isopod (Crenoicus sp.) has been netted in both the Imperial resurgence and in Paradox Cave by Eberhard. It is likely stygophilic but has not been further studied.

Order Amphipoda
Eberhard trapped the eusirid amphipod Pseudomoera fontana (Sayce, 1902) in both the Northern Stream sink and the Imperial Cave resurgence; it is a common species in southeast Australian streams and is either an accidental or stygophile.

Neoniaphargid amphipods were trapped in both Paradox Cave and the Imperial streamway. Bradbury and Williams (1997) described the stygobitic Neocrypta simoni based on the material collected by Stefan Eberhard in Paradox Cave (Fig. 4f); five specimens netted in the Imperial River by Gibian, Smith and Wheeler have not been identified as yet.

Order Anaspidacea
Eberhard (1993) collected stygobitic syncarids (Psammaspidae) by placing baits (kippers in brine) in the Imperial and Spider Cave rivers and in perched seepage fed pools well above the river level. Mia Thurgate collected more from the Pool of Reflections in River Cave in 2000. Psammaspidids (Fig. 4g) are a primitive group of eyeless crustaceans recorded from ground waters in eastern Australia. No further taxonomic work has been conducted on this interesting material.

MOLLUSCA

Class Gastropoda
Pommerhelix depressa (Hedley, 1901) and Elsothera sericatula (Pfeiffer, 1849) have been collected in Casteret Cave and caves in the southern limestone. Eberhard collected the aquatic snail Glacidorbis hedleyi Iredale, 1943 at the Imperial resurgence. Snails collected by Gibian et al. (1988) have not been examined.

ANNElidA

Terrestrial and aquatic oligochaetes were reported by Gibian et al. (1988) and Eberhard (1993) but not further identified.

NEMATOMA

Terrestrial and aquatic nematodes were reported by Gibian et al. (1988) and Eberhard (1993) but not further identified.

PLATYHELMINTHES

Flatworms of the Orders Paludicola and Terricola were reported by Eberhard from Wiburds Lake, Mammoth and Serpentine Caves.

DISCUSSION

Comparisons of biodiversity patterns between different karst areas can be fraught with biases including, inter alia, area effects and differences in survey effort, methods and taxonomic biases, as well as bias towards troglobitic/stygobitic species, incorrect ecological classification, provincialism and other fallacies (see Culver et al. 2013). Nevertheless we consider it timely to undertake a brief re-appraisal of Jenolan’s cave fauna to place its significance in a regional and national context, especially because a great deal of subterranean fauna research has occurred elsewhere in Australia (see Guzik et al. 2011) since the previous Jenolan and New South Wales inventory by Eberhard and Spate (1995); Thurgate et al. (2001a, 2001b).

Jenolan retains its status with the highest
recorded subterranean taxonomic diversity (136 taxa) of any karst area in New South Wales, which is at least partly an artefact of high survey effort, with Jenolan drawing the attention of biologists over many decades. Notwithstanding, we hypothesise that other environmental factors may be responsible. Firstly, Jenolan is highly karstified and hosts the most extensive cave system in New South Wales with over 40km of surveyed cave passage. This subsurface ‘area effect’ is consistent with studies elsewhere (e.g. Graening et al. 2006) which show increasing cave length correlates with increasing species richness. Secondly, Jenolan is a topographically diverse fluvial karst with many large-sized cave entrances (vertical and horizontal) and multiple sinking streams which facilitate active colonisation of caves by animals, but also particularly, their passive transport underground (by gravity, water or air), which may partly account for the high proportion (53%) of taxa classified as ‘cave accidentals’ in our inventory. This ratio is not dissimilar to 42% recorded in a desktop bio-inventory of the Nullarbor which is a significantly larger karst area (by > 2 orders magnitude) but similarly characterised by multiple large-sized cave entrances where collecting efforts have historically tended to focus (Eberhard in litt.).

While the classification of taxa as ‘accidentals’ or otherwise (trogloxene, troglophile, troglobite) is often necessarily inferred owing to limitations in survey data and knowledge of species taxonomy and ecology, ambiguous classification or misinterpretation of trogломorphic traits may skew interpretation of site ‘significance’ when assessed in terms of total species richness. For this reason, many comparisons between karst areas in the literature are restricted (arguably biased) towards trogломorphic species (presumed troglobites and stygobites, see Culver and Sket 2000). Notwithstanding, troglobites and stygobites are more typically short-range endemic species and therefore more vulnerable to threats and extinction from environmental changes. On this basis a high conservation significance may be attributed to troglobites and stygobites.

In paving the way for standardized and comparable subterranean biodiversity studies, Culver et al. (2013) concluded that it is necessary to treat troglobites and stygobites differently from non-obligate species, because differences of opinion exist as to which species are troglobites and stygobites. In our opinion the eight species considered likely to be troglobites or stygobites at Jenolan (revised from 14 trogломorphic species earlier reported by Thurgate et al. 2001a) ranks as fairly typical for karst areas in the eastern highlands (Eberhard and Spate 1995). At this point in discussion it is appropriate to correct an error in the Jenolan Karst Conservation Reserve Draft Plan of Management (Department of Environment and Conservation NSW, undated, p. 49) which mistakenly reports 147 species of troglobitic [sic] fauna.

We consider it likely that additional obligate subterranean species remain to be discovered at Jenolan, especially in the poorly sampled epikarst, vadose, deep phreatic and interstitial aquatic habitats, and terrestrial meso-cavern habitats. Our prediction is based partly on the diversity known from Wombeyan Caves, located 55 kilometres south of Jenolan, which has a high diversity (11 species) of stygobitic amphipods (Bradbury and Williams 1997). For comparison, the richest obligate cave fauna recorded from eastern Australia is Bayliss Cave, a lava tube in north Queensland, with 20 species of troglobites (Culver and Sket 2000). Tasmania is also relatively diverse with 15 or more obligate species recorded from well-developed karst areas (Eberhard 1996).

The fallacy of provincialism as termed by Culver et al. (2013) occurs when data from one ‘favoured’ place is treated differently than data from other places. In applying the metaphor ‘from rags to riches’ to highlight subterranean biodiversity in New South Wales, Thurgate et al. (2001a) may have been justifiably optimistic, however, this paradigm deserves to be reappraised in the national context considering subsequent discoveries of remarkably diverse subterranean faunas in other states. Recently in Western Australia sampling of deep groundwater aquifers has revealed the existence of diverse (> 60 species) stygobitic communities (e.g. Eberhard et al. 2009). Sampling of terrestrial meso-cavern habitats in iron-ore and calcrite rocks has also revealed highly diverse troglobitic communities comprising > 45 obligate species (S. Eberhard in litt.).

FUTURE RESEARCH AND CONSERVATION PRIORITIES

The Jenolan Karst Conservation Reserve Draft Plan of Management (Department of Environment and Conservation NSW, undated) recognises that cave fauna is highly susceptible to disturbance and recommends further investigation into the potential impacts of human activities on the conservation of these species. The material from the 1986-1993 collections represent a reasonable baseline survey for Jenolan Caves. Nevertheless cave fauna, especially the highly adapted species, are usually rare and it is highly likely that further intensive collection efforts would result in new taxa being found. Alternative
INVERTEBRATE CAVE FAUNA OF JENOLAN

collection techniques used for aquatic micro-fauna and terrestrial meso-cavern habitats e.g., damp leaf litter packs (Weinstein and Slaney, 1995) should be evaluated as they may effectively sample taxa that were not collected using the methods previously employed. The current state of knowledge, gaps and research priorities are summarised in Table 2.

A great deal of the material collected has not yet been sorted to species level. New species still await formal description due to the very limited funding and diminishing taxonomic resources available in Australia. Future collection efforts could concentrate on obtaining specimens of groups where a funded taxonomist is available, or aim to increase the number and quality of specimens of certain important troglobitic and stygobitic representatives (e.g. by obtaining more mature material, including both sexes) or seek information on their biology and ecology, about which virtually nothing is known.

The species of most conservation interest are those species restricted to the subterranean environment, especially the troglobites and stygobites. The physical extent and degree of karstification at Jenolan, and the hypothesised presence of undiscovered troglobitic and stygobitic taxa in the mesocavern and other cryptic aquatic habitats, emphasises the importance of the continuing biological exploration of this significant subterranean ecosystem.

ACKNOWLEDGEMENTS

We would like to thank Louise Smith (previously L. Wheeler), the Jenolan Caves Reserve Trust and the Australian Museum for their support with the 1986-93 collection work and especially Ernest Holland for his supervision, support and advice. We are indebted to the following taxonomists who have worked on the Jenolan fauna: Dr Chris Allen, Dr Max Beier, Dr John H. Bradbury, Dr Cathy Car, Dr Peter Cranston, Dr Alison Green, Dr Penelope Greenslade, Dr Bruce Halliday, Mr Danilo Harms, Dr Mark Harvey, Dr Lionel Hill, Dr Glenn Hunt, Dr Tomislav Karanovic, Dr Robert Mesibov, Mr Graham Milledge, Dr Barry Moore, Dr Ebbi Nielsen, Dr Winston Ponder, Mr Peter Serov, Dr John Stanisic, Dr Michael Rix, Professor William (Bill) Williams, Dr George (Buz) Wilson.

- Gibian et al. (1988); AMS (KS.96021, KS.96025, KS.96031, KS.96033, KS.96035-36, KS.102761-62)

**Family Dalodesmidae**

- Undetermined dalodesmids
- RM N Tp
- Devil’s Coach House, Hennings (entrance chamber), Serpentine, Mammoth (Sand Passage, Horseshoe Cavern)
- Gibian et al. (1988); material collected by Smith, Wheeler, Gibian, Eberhard, in AMS (KS.96009, KS.96022-23, KS.96026-27, KS.96029, KS.96032, KS.96034, KS.96038, KS.106995)

### CLASS ARACHNIDA

**Order Araneae**

**Family Cycloctenidae**

- Cycloctenus abyssinus
- Urquhart, 1890
- MG N Tp
- Described by Urquhart (1890) from the Jenolan Caves (females).
- Male described by Rainbow (1893) - not located in AMS collection
- Paradox, Mammoth, Hennings (bat guano or wandering over rocks, often in entrance chamber)
- Gray (1973); Gibian et al. (1988); material collected by Smith, Holland, Eberhard, Marx and Wheeler in AMS (KS.10222, KS.18274, KS.21855, KS.23495, KS.35009)
**Badumna socialis**
(Rainbow, 1905)

**Family Theridiosomatidae**

| *Baalzebub* sp. | MG | N | Tp | Females and juveniles. Referred to in Gray (1973) as Theridiosomatid gen. nov. sp. nov. | Chifley, Elder, Paradox, Hennings, Serpentine, Casteret; usually areas with light breezes; common cave frequenting genus but also found in sheltered surface localities | Gibian et al. (1988); material collected by Gray, Holland, Smith, Gibian, Eberhard, Renwick, Wheeler in AMS (KS.10444, KS.17827, KS.17841, KS.18275, KS.19021, KS.19044, KS.19047, KS.21856, KS.35008, KS.73233) |

**Family Uloboridae**

| *Philoponella pantherina* (Keyserling, 1890) | MG | ? | Tp? | | Chifley, Lucas, Grand Arch | Gray (1973); Gibian et al. (1988); specimens collected by Gray and Gibian in AMS (KS.10227, KS.17826, KS.17836, KS.21861) |

**Order Opiliones**

**Family Triaenonychidae**

| *Holomuncia cavernicola* Forster, 1955 | GH | MG | N | Tp | Described by Forster (1955b) from material collected at Jenolan Caves. Hamilton-Smith (1967) also listed Yarrangabilly, Wyanbene and Wombeyan as locations for species. Hunt (1992) examines additional material from Jenolan and redescribes the species (and the genus for which *H. cavernicola* is the type species) | Chifley, Imperial, Devil’s Coach House, Hennings, Cerberus, McKaowns Hole, a Southern Limestone cave, Temple of Baal, Paradox and several epigean specimens from the Jenolan area; tentatively also a specimen from Tuglow Caves. Pigmentation and eye mound size varies between cave and surface populations | Hunt (1992); Forster (1955b), types in AMS (KS.6912, KS.6914); Gibian et al. (1988) other material collected by Hunt, Gray, Clark, Gibian, Eberhard, Smith, Wheeler, Dew, Guides and ‘Speleo Club’ in AMS (KS.5077, KS.17829, KS.19033, KS.19048, KS.19050, KS.21402-04, KS.21857, KS.23216, KS.35027) |

**Family Neopilionidae**

| *Megalopsalis* sp. | GH | MG | Ac | Listed as *Spinicrus* by Gibian et al. (1988); genus is now considered to be a junior synonym of *Megalopsalis* | Mammoth | Gibian et al. (1988) specimens collected by Pickering and Gibian in AMS (KS.19032, KS.35027) |
**Proc. Linn. Soc. N.S.W., 136, 2014**

S.M. EBERHARD, G.B. SMITH, M.M. GIBIAN, H.M. SMITH AND M.R. GRAY

**Acarina**

**Family Ascidae**

*Proctolaelaps holmi*  
(Halliday, 2001)  
BH N Tp  
Described from material collected by E. Holm at Jenolan  
Lucas (bat guano)  
Halliday (2001); 10♀♀; types in ANIC

*Proctolaelaps pygmaeus*  
(Müller, 1859)  
BH I/C Tp?  
Cosmopolitan species described from a cave in Germany  
Lucas (bat guano)  
Halliday (2001); 4♀♀ ANIC

**Family Digamasellidae**

*Dendrolaelaps adelaideae*  
Womersley, 1954  
BH N Ac  
Devil’s Coach House (overflow passage) (litter), Serpentine (litter), Paradox (guano)  
Halliday (2001); 1♂♂ 2 DN; ANIC

**Family Laelapidae**

*Stratiolaelaps scimitus*  
(Womersley, 1956)  
BH N Tp?  
Originally identified in Halliday (2001) as *Stratiolaelaps miles* (Berlese, 1892) which was thought to be the same as *S. scimitus*; they are now known to be different species (Halliday in litt. 2013)  
Lucas (guano); soil dwelling predatory mite  
Halliday (2001); 11♂♂ 4DN 2PN (laboratory reared progeny); ANIC

Several species of  
*Gaeolaelaps* Evans and Till, 1966  
BH  
This family very difficult taxonomically so far identification of these species still required (Halliday in litt. 2013)  
Halliday (in litt. 2013); ANIC

**Family Macrochelidae**

*Geholapsis mandibularis*  
(Berlese, 1904)  
BH I/C Ac  
Devil’s Coach House (overflow passage), Serpentine, Bow, Mammoth (Horseshoe Cavern, Sand Passage) (litter); previously only recorded from Europe where it is widespread and abundant  
Halliday (2001); 25♂♂ 14DN 8PN; ANIC

*Macrocheles tenuirostris*  
Krantz and Filipponi, 1964  
BH N Tp  
Paradox (guano); subterranean species found in caves and animal burrows in SE Australia  
Halliday (2001); 1♀; ANIC

**Family Ologamasidae**

be part of *Megalopsalis*  
KS.97658)
