Abstract

A root parasitic plant, Christisonia mira J.Mathew (Orobanchaceae) is described as a new species from the Kerala part of southern Western Ghats, India.

Introduction

Christisonia Gardner is an achlorophyllous (holoparasitic) genus comprising c. 17 species distributed in India, Sri Lanka, Laos, SW China, Thailand and Malesia (Nickrent 2012). According to Benniamin et al. (2012), ten species of Christisonia have been recorded in India, of which, six species viz., C. bicolor Gardner, C. calcarata Wight, C. indica Anil Kumar, C. keralensis Erady, C. neilgherrica Gardner and C. tubulosa (Wight) Hook.f. are recorded from the Kerala part of the Western Ghats (Nayar et al. 2014). Sasidharan (2013) indicated that C. indica and C. tubulosa are endemic to the southern Western Ghats; C. bicolor and C. neilgherrica (=Campbellia cytinoides Wight) are Indo-Sri Lanaka linkage taxa; C. calcarata is a south Indian element and, C. keralensis is a southern Western Ghats, north east element. Mathew and George (2015) recently added C. tomentosa J.Mathew & K.V.George, as new from the Kerala part of southern Western Ghats. Botanical explorations in the Achankovil forests during 2009–2014 yielded specimens of Christisonia that we feel are sufficiently distinctive to warrant taxonomic recognition as a new species. Christisonia mira J.Mathew is here described and illustrated.

Taxonomy

Christisonia mira J.Mathew, sp. nov. (Figs 1–4)

Diagnosis: Christisonia mira is morphologically most similar to C. bicolor Gardner, but differs from that species in having: a red, 4 cm long corolla (corolla yellow, 6 cm long in C. bicolor); bracteoles elliptic to oblanceolate, 5 mm long (8 mm long, lanceolate or acute in C. bicolor); racemes of 8 or 9 flowers (racemes of 5 or 6 flowers in C. bicolor), and stamens non didynamous and 2.5–2.7 cm long (stamens didynamous, 3–3.5 cm long in C. bicolor). C. mira is also morphologically similar, with similar ecological preferences to those of C. tomentosa and C. neilgherrica but differs from these species as indicated in Table 1.

Type: India, Western Ghats, Kerala, Kollam district, Vellakkaltheri, altitude 1800 m, 9°07’11” N, 77°13’05” E, 9 Jun 2012, Jose Mathew 3076 (holo: MH; iso: TBGT).
Herbs, erect to 5–6 cm, achlorophyllous, parasitic on the roots of *Strobilanthes luridus* Wight., hairy. Roots very numerous, wiry, profusely branched, up to 1.5 mm thick, with haustoria at the place of contact with the host roots and developing many adventitious buds. Stem unbranched, with whorled, ob lanceolate bracts. Inflorescence racemose, 8- or 9-flowered. Bracts 5 mm long, 2–3 mm wide, light brownish, glabrous. Pedicels 1 cm long, 3–5 mm thick, erect, pink. Bracteoles 2, elliptic to oblanceolate, 5 mm long, 3 mm wide. Flower buds glandular hairy, covered with copious translucent tasteless slime when young. Calyx 5, 1.2 cm long, 0.6–0.8 cm wide, base creamy white, lobs red, tubular-campanulate with slight median zygomorphy, tube split at the top to one third the length into 5 subequal triangular valvate lobes with acute apex. Corolla tube 3–3.5 cm long, red-coloured, trichomes on both sides, lower half closely appressed to the ovary, upper half inflated; throat yellowish with a tinge of orange; tube expanding into a sub-bilabiate 5-lobed limb; lobes 0.8–1 cm long, orbicular reniform, imbricate, anterior three lobes somewhat equal and slightly smaller than the posterior lobes. Stamens 4, inserted at the constricted part of the corolla tube, included, non didynamous; filaments light purplish, 2.5–3 cm long, glandular hairy throughout; anthers pale purplish, two-celled, one of the cells fertile, ovate, base sharply spurred with tip curved outwards; connective with a prominent swelling on one side. Pollen grains with smooth wall. Ovary of 2 median carpels, syncarpous, superior, unilocular with a tendency to become bilocular at the base; placentae 2, parietal, bipartite, tips expanding into fleshy portions; ovules 180–200 μm long, 125–150 μm broad, numerous, anatropous and arising from the entire surface of the placenta; style glabrous, 3–3.5 cm long, included but reaching above the level of the anthers; stigma peltate and with a narrow depression in the centre. Fruit a capsule, pyriform, ca 1.4 x 1.8 cm, unilocular, enclosed by persistent calyx. Seeds minute, numerous.

**Other specimen examined:** INDIA: KERALA: S Western Ghats, Kollam district, Vellakkaltheri, 9 Jun 2013, *Jose Mathew 3094, 3095* (TBGT).

**Etymology:** The specific epithet ‘mira’ refers to the wonderful appearance of this new species.

**Distribution and ecology:** *Christisonia mira* is endemic to the Southern Western Ghats, currently known only from two localities from Vellakkaltheri in the Kollam district (Fig. 1). The species grows on the wet roots of...

427

**Strobilanthes luridus** Wight at altitudes of c. 1800 m. It is found in association with *Ophiopogon intermedius* D.Don (Asparagaceae) and *Elatostema acuminatum* (Poir.) Brongn. (Urticaceae).

**Flowering:** Flowers and fruits in June.

**Conservation status:** *Christisonia mira* is currently known only from 2 localities of Achankovil reserve forest area (Vellakkaltheri in the Kollam district), each separated by 800 m. A total of 90 mature individuals were found in the area. The data gained from the field studies were evaluated according to the IUCN (2015) categorization and at least “vulnerable” status has been proposed for the species.

**Remarks:** *Christisonia mira* is a holoparasite growing on the roots of *Strobilanthes luridus*. *Christisonia tomentosa*, also grows on the roots of the same host at northern Achankovil. *Strobilanthes luridus* is an endemic species, occupying a very restricted area in the evergreen forests of southern Western Ghats (Sasidharan 2013). Thorogood et al. (2007) evinced that host specificity is a driving force in the evolution and speciation of parasitic plants. An enhanced understanding of the evolution, cell biology, and physiology of host specificity in this, and related taxa is crucial.
